

11.3 Presenting and analysing data

1 What is the difference between bar graphs, divided bar graphs and histograms?

2 Decide if the following statements are true or false. If they are false, correct them:

- a** Pie charts show data as percentages.
- b** Only one line can appear on a line graph.
- c** Climate graphs are an example of a combined graph.
- d** Scatter graphs can also be called dispersion graphs.
- e** Doughnut graphs use symbols to represent each category of data.
- f** Triangular graphs represent the relationship between two variables.
- g** Radial graphs can be useful for showing outliers.

3 Copy the following text and complete by choosing the correct word in the brackets.

When interpreting graphs, it is important to read all information given, such as axes labels, (**titles/samples**) and the units used. You should look for data that is unusual, such as (**highs/gaps**) and (**errors/lows**) and determine if there is a trend – this will help you to decide whether the data agrees or disagrees with the hypothesis and reach a (**method/conclusion**).

4 Students are collecting data about rates of erosion along a stretch of coastline. Suggest a suitable technique that they

could use to present this data. [1]

5 A group of students have visited a local mine to identify how industry impacts the local environment. They have collected qualitative data in the form of words. Suggest how they could present this data. [1]

6 A class have been researching how many people in their local town work in the primary, secondary and tertiary sector. Suggest a suitable way to present this data. [1]

UNDERSTAND THESE TERMS

- Categorical data
- Outlier
- Quantitative data
- Trend
