

2.1 Physical processes that shape the coast

Understanding the types of processes that shape the coast is important. Test your knowledge on the physical processes that shape the coast using the questions below. There is some overlap with river processes so make sure that you are referring to the appropriate environment in your responses.

1 Sort the following terms into 'erosion processes' or 'deposition processes'.

- hydraulic action
- longshore drift
- corrasion
- a wave losing energy and dropping material on a beach
- formation of a spit
- corrosion

2 Decide if the following statements are true or false:

- a** Swash carries sediment down the beach.
- b** Longshore drift is influenced by the direction of prevailing winds.
- c** Suspension involves large pebbles rolling along the seabed.

3 How does wave refraction help to form headlands and bays?

4 Produce a labelled diagram of a destructive wave, showing its main characteristics.

UNDERSTAND THESE TERMS

- Hydraulic action
- Corrasion
- Corrosion
- Swash
- Spit
- Suspension
- Wave refraction
- Longshore drift
- Destructive wave
- Headland
- Bay

'Describe' questions require you to give the main characteristics of something. For example, when describing how sediment moves down the coast, you need to state **how** this occurs. You do not need to explain **why**. When describing a figure, you need to 'say what you see'. Only use the resource. There is also no need to give reasons for the trends or patterns that you can see, as that would be explaining.

~~5~~ Describe how sediment is moved along the coast. [5]

~~6~~ Study Figure 2.1. Describe the impacts of installing groynes on this coastline shown in Figure 2.1. [5]

Figure 2.1: A beach with wooden groynes
